

Mint-to Logic - Prototype Summary Brief

Overview

Mint-to Logic is a lifecycle validation protocol developed and protected under provisional patent by Spencer Southern. It governs identity-bound verification tokens called Mint Units that burn after use. This prevents fraud, double-entry, or unauthorized reuse across systems like digital voting, event ticketing, or cyber access. The protocol works offline and is blockchain-independent. A functional backend prototype has been developed, which logs issuance, validation, and burn events with timestamped integrity.

Key Features

- Lifecycle enforcement: Verify -> Burn -> Log
- Offline-capable and secure
- Configurable retry, burn, and Limbo logic
- Generates Shepherd Coin metadata upon lifecycle completion
- Adaptable to multiple verticals (voting, ticketing, identity access, cybersecurity)
- Demonstrated in ValiPass prototype (available for review under NDA)

What I'm Seeking

Support with grant alignment, funding strategy, or incubator opportunities to help finalize the full patent, expand prototype development, and prepare for commercialization while completing academic studies.
